The key to this pamphlet is the story of a 12 year old boy who is so badly asthmatic that he needs oxygen to survive. About the author Mary Nelson got her undergraduate degree in English from the University of Iowa. M J M Acute respiratory distress syndrome is a syndrome characterized by acute and progressive dyspnea and hypoxemia due to diffuse, bilateral pulmonary infiltrates. This may result in hypotension, shock, cardiac arrest, and death. There are two types of ARDS: acute lung injury (ALI), and acute respiratory distress syndrome (ARDS). Acute lung injury (ALI) occurs early in the course of ARDS. The following risk factors have been associated with the development of ALI: ventilator-induced lung injury, aspiration, infections, and post-surgical trauma. The hallmark of ALI is a pulmonary inflammatory response that can result in diffuse alveolar damage. Alveolar damage

results in increased capillary permeability and protein-rich oedema in the alveolar spaces. The process is activated by a combination of injurious mechanical forces, increased capillary hydrostatic pressure, and pulmonary surfactant abnormalities. The accumulation of activated neutrophils in the pulmonary interstitium and airspace results in the release of reactive oxygen species and proteolytic enzymes. These activate the coagulation cascade, with resultant intravascular microvascular thrombi, increased pulmonary vascular resistance, and hypoxemia. The clinical presentation of ALI includes the signs and symptoms of acute respiratory distress, including tachypnea, paradoxical breathing, decreased oxygen saturation (SpO₂), use of accessory muscles, and respiratory distress.
